

Problem Set 5

Question 1 PP 439-440

Real exchange rate, $\varepsilon = \frac{EP}{P^*}$

And hence % change in real exchange rate,

$$\% \Delta \text{ in } \varepsilon = \% \Delta \text{ in } E + \% \Delta \text{ in } P - \% \Delta \text{ in } P^*$$

When nominal exchange rate is fixed, $\% \Delta \text{ in } E = 0$

$$\% \Delta \text{ in } \varepsilon = \% \Delta \text{ in } P - \% \Delta \text{ in } P^*$$

$$\% \Delta \text{ in } \varepsilon = \pi - \pi^*$$

(a) If foreign economy is in medium run eqm, then $y^* = y_n^* \Rightarrow \pi^* = \bar{\pi}^*$

(b) Suppose $\bar{\pi} = \bar{\pi}^*$, then

$$\pi - \bar{\pi} = \left(\frac{\alpha}{L}\right)(Y - y_n) \Rightarrow Y = y_n \text{ and } \pi = \bar{\pi}$$

$$\pi^* - \bar{\pi}^* = \left(\frac{\alpha^*}{L^*}\right)(Y^* - y_n^*) \Rightarrow Y^* = y_n^* \text{ and } \pi^* = \bar{\pi}^*$$

$$\pi = \pi^* = \bar{\pi} = \bar{\pi}^*$$

(c) When domestic currency is overvalued, domestic goods are made relatively expensive, the NX is low. Then, $NX < 0$ and $Y < Y^*$.

Initially $IS = IS_0$ and $LM = LM_0$. Eqm at pt O. $Y = Y_0 < Y_n$ and $i = i_0$ and $NX_0 < 0$

As $Y < Y_n \rightarrow$ Recessionary gap $\rightarrow$ In the medium run, $P \downarrow$ and $\varepsilon = \frac{EP}{P^*} \downarrow$

Real dep $\rightarrow$ x cheaper $\rightarrow x \uparrow \rightarrow NX \uparrow \rightarrow IS (IS_0 \rightarrow IS_1)$
 $\rightarrow$ M expensive $\rightarrow M \downarrow$

- (d) Same as (c). Immediate devaluation $\rightarrow$ real dep $\rightarrow \epsilon \downarrow \rightarrow NX \uparrow \rightarrow \rightarrow$
 $\rightarrow$ IS and the economy returns to Y_n immediately rather than gradually
 through P $\downarrow$

- (e) Under fixed exchange rate, $i = i^*$.
 In the period of devaluation, the return on domestic bonds is lower than
 the return on foreign bonds.
 It is hard to know if the bondholders will believe the devaluation is
 one-time only. If they believe another devaluation is possible,
 then it will be higher than foreign interest rate.

$$\begin{aligned} \pi^* &= \pi^* \text{ and } Y^* = Y^* \Rightarrow (Y^* - Y^*) \left(\frac{\pi^*}{Y^*} \right) = \pi^* - \pi^* \\ \pi^* &= \pi^* \text{ and } Y^* = Y^* \Rightarrow (Y^* - Y^*) \left(\frac{\pi^*}{Y^*} \right) = \pi^* - \pi^* \end{aligned}$$

(c) When domestic currency is overvalued, domestic goods are more relatively
 expensive, the Y is low. Then, $NX < 0$ and $Y < Y_n$.

Initially $IS = IS'$ and $LM = LM'$. Eqm at P_0 . $Y = Y_0 < Y_n$ and $i = i_0$ and $NX < 0$.
 As $Y < Y_n \rightarrow$ recessionary gap $\rightarrow$ in the medium run, $P \downarrow$ and $\epsilon = \frac{P}{P^*} \downarrow$
 $\rightarrow$ Real dep $\rightarrow X \uparrow$ cheaper $\rightarrow NX \uparrow \rightarrow IS \uparrow$ (to IS')
 $\rightarrow$ i expensive $\rightarrow$ $W \uparrow$

Question 2

The UIP suggests that

$$i_t = i_t^* - \frac{E_{t+1}^e - E_t}{E_t}$$

Expected dep rate of foreign currency

If $i_t = 5\%$ and $i_t^* = 4\%$, for financial investors to hold both domestic and foreign bonds, $\frac{E_{t+1}^e - E_t}{E_t} = -1\% \Rightarrow$ Exp. dep rate of foreign currency is -1%
Exp. app rate of foreign currency is 1%

(a) If $i_t^* = 3$, $E_t = 0.5$ and $E_{t+1}^e = 0.5$

Expected dep rate of foreign currency, $\frac{E_{t+1}^e - E_t}{E_t} = 0$

Then $i_t = 3$

(b) In period 2, when crisis begins, $i_t^* = 3$, $E_t = 0.5$ but $E_{t+1}^e = 0.45$

Expected dep rate of foreign currency, $\frac{E_{t+1}^e - E_t}{E_t} = -10\%$

Expected dep rate of domestic currency is 10%

$$i_t = 0.03 - \frac{(0.45 - 0.5)}{0.5}$$

$$i_t = 0.13 \text{ or } 13\%$$

(c) The resolution of the crisis in period 4 occurs when beliefs change about the expected future exchange rate i.e. $E_{t+1}^e = 0.5$ again. The peg becomes credible.

(d) In period 5, $\frac{E_{t+1}^e - E_t}{E_t} = \frac{0.4 - 0.5}{0.5} = -20\%$

Expected dep rate of domestic currency is 20%

$$i_t = 0.03 - \left(\frac{0.4 - 0.5}{0.5} \right)$$

$$i_t = 0.23 \text{ or } 23\%$$

The domestic interest rate has to rise to 23% to maintain UIP. It only rises to 15%

which is not sufficient. To prevent dep, central bank has to buy domestic currency and sell foreign reserves. Foreign reserves at the central bank will decrease.

devaluation of foreign currency

- (d) Since $E_t = E_{t+1}^e = 0.4$ instead of 0.5, this means that a devaluation has occurred. It may be difficult for the gov./central bank to convince bondholders that they will never devalue again.

(a) if $E_t = 0.5$, $E_{t+1}^e = 0.5$ and $E_{t+2}^e = 0.5$

Expected dep rate of foreign currency: $E_{t+1}^e - E_t = 0$

Then $i = 0$

(b) In period 2, when crisis begins, $i_t = 0$, $E_t = 0.5$ but $E_{t+1}^e = 0.45$

Expected dep rate of foreign currency: $E_{t+1}^e - E_t = -0.05$

Expected dep rate of domestic currency is 10%

$$i_t = 0.03 - (-0.05 - 0.05) = 0.13$$

$$i_t = 0.13 \text{ or } 13\%$$

(c) The resolution of the crisis in period 4 occurs when beliefs change about the expected future exchange rate, i.e. $E_{t+4}^e = 0.5$ again. The Fed becomes credible.

(d) In period 5, $E_{t+1}^e - E_t = 0.4 - 0.5 = -0.1$

Expected dep rate of domestic currency is 20%

$$i_t = 0.03 - (0.4 - 0.5) = 0.08$$

$$i_t = 0.08 \text{ or } 8\%$$

The domestic interest rate has to rise to 8% to maintain LRP. It only rises to 10
